PATCHING • CABLE ASSEMBLIES • CONNECTORS

T14A

INTRODUCTION

The equipment and components displayed in this catalog are based on a need to provide standard system interface patching so that the many end equipments available from other manufacturers could be interconnected and programmed with a minimum of engineering, space and cost. The available items consist of Patch Panels, Patch Cords, Cable Assemblies, Jacks, Looping Plugs, Power Dividers, RF Connectors, and A-B Data Switches.

All items are manufactured to meet the highest standards of industry and government and carry a one year guarantee. All of our components meet or exceed the appropriate military specifications, MIL-C-39012, and in one case, the specification MIL-C-49142 was developed from our commercial parts.

Military items are supplied under the ADCP (Acquisition and Distribution of Commercial Products) program, DOD Directive No. 5000-37 dated September, 1978, rather than by QPL. Those using military requisitions and desiring only Trompeter parts can initiate a "no substitution" restriction by simply inserting the numeral "2" under Item 65 and the letter "B" under Item 66.

Consideration is also given to avoiding unwanted noise and interference via equipment interconnecting cables, with provision to isolate signal return lines from ground. This is accomplished by using isolated coax, twinax, triax or quadrax cable and components for system shielding and common mode isolation and rejection.

APPLICATIONS

Computers - TV Broadcast - CATV - CCTV - ETV - Communications - Telephone - Missile and Space Telemetry - Aircraft - Nuclear and Industrial Instrumentation - Process Controls - Security Equipment - High Rise Fire Prevention - Automatic Testing - Information Retrieval - Microwave and Digital Data Transmission.

SYSTEM DESIGN TECHNICAL PAPER - Page 2
NEW PRODUCTS AND ADDITIONS - Pages 19, 23, 32, 33, 34, 35, 45 and 46

NOTE: Most items shown 1:1 scale.

ELECTRONIC SYSTEMS
WIRING AND CABLING

After buying the most expensive "end" equipments, many systems engineers have difficulty in determining the best methods of cabling, interconnection and routing of signals from place to place, with the minimum of loss, degradation and noise pickup. Often, simple solutions such as selecting the correct cable, eliminating common mode grounds or space separating long runs of parallel cables will make the difference between a good or bad system. It must be emphasized that these and other good practices must be implemented at the time of initial design and are almost impossible to install after the system is built. This "interface" engineering will be discussed in two subsequent sections (1) Signal Degradation; (2) Noise.

As an introduction, the systems engineer should study his system parameters and noise environment before selecting his interface components. Consideration must be given to (a) signal frequencies, whether audio, video, I.F. or R.F. (b) voltage and power levels (c) tolerable losses or degradation, including the possibility of reflected signals due to discontinuities (d) pickup of noise from direct contact common mode and ground loop returns, or radiated stray magnetic and capacitive fields.

Due to the susceptibility of circuit wiring and cabling to the pickup of noise, all **low** voltage level wiring should be shielded irrespective of frequency to be transmitted. Coax cable, although primarily designed to carry R.F., is excellent to use as low frequency shielded wire since it is relatively inexpensive (RG-58, RG-122, etc.) and many complete series of coax connectors are readily available.

For higher frequencies, coax cable **must** be used for point to point wiring since it has the transmission characteristics, flexibility and economy necessary for most systems. At this point it might be enlightening to some readers to explain the various impedance standards of 50, 75 and 93 Ω coax cables. The most efficient impedance to use when transmitting any signal considering the voltages, currents and powers to be transmitted is 75 Ω , and would be the only standard if these were the sole considerations. The telephone industry, followed by the TV industry, use 75 Ω almost exclusively for the transmission of video, baseband and I.F. frequencies. The military services during the period 1920 through 1940, were faced with a differing need for low radiation angle omnidirectional antennas for broadcasting ship to ship, airport tower to low flying aircraft and base station to ground troops. The only antenna that would give this performance was the **vertical ground plane** in its many forms, which turned out to be 50 Ω . The military standardized on 50 Ω impedance and spent vast sums of money developing cables and connectors for all of their coax systems. At one time a military agency, Armed Services Electro Standard Agency (ASESA) designed all military coax components and assigned the connector UG and cable RG designations. This has since been replaced with the latest government/industry committees cooperating and producing the current general connector standard MIL-C-39012 primarily for 50 Ω usage. 93 Ω cable came about due to the need for low capacitance instrumentation coax cable. By simply removing **some** of the coax dielectric and substituting air in RG-59, the distributed capacitance was lowered, thereby creating a lower loss **voltage** transmission medium RG-62.

More sophisticated cables and connectors of twinax, triax and quadrax are now available to improve external noise rejection, or to contain classified signals and keep them from becoming a security compromise as will be described later.

To successfully complete any signal transmission system, the engineer must move the various signals from place to place with (1) minimum signal degradation and loss, (2) reduce unwanted external noise to an acceptable level or a mix of 1 and 2. The discussion that follows applies generally to all frequencies of data, video, I.F., and R.F.; however, each case must be studied and considered by itself with the proper remedies applied.

1. Signal Degradation

Signal degradation in any transmission medium usually consists of voltage amplitude reductions, wave shape changes, phase or delay changes, or power losses where power is transmitted. Since the interconnecting cable is the longest transmission path in most systems, its selection, manufacture, testing and installation should be carefully considered and not randomly selected and installed as is the usual practice. When selecting cable from specifications, always consider the length of the cable run, heat exposure, frequency and power to be transmitted vs. the acceptable losses inherent in the cable, the external noise fields and frequencies to be anticipated or encountered, and the easy availability of connectors to terminate the cable. Too small a cable will always be cause for excessive losses. Fast rise time digital pulses will have the leading edge distorted due to the high resistance "skin" effect of small coax cables. When selecting a cable for a long run, observe the insertion loss to assure that your signal gets to its destination without too much loss. When in doubt choose a bigger cable! Incomplete copper coverage in the outer braid over the dielectric will also cause transmission line losses as well as cable susceptibility to signal leakage or noise pickup. Unseen manufacturing faults produce signal path impedance changes or discontinuities which can only be detected by "frequency sweeping" the cable. TV broadcasters have encountered as high as 60 dB losses in short runs due to periodicity and other manufacturing faults detectable only by swept frequency testing techniques. Many cable defects are not readily visible and may not show up without proper testing. In buying coax cable, the reputation of the manufacturer, type, quantity and quality of material used is more important than the few pennies saved buying the cheapest unknown brand. In system design, be careful that the cable does not support equipment or is subject to prolonged exposure to heat. Do not tightly "bundle" cables so as to cause cross talk, and do not bend beyond the manufacturers recommended radius of bend which could produce cable discontinuities. When routing cables try to space separate high signal level or power circuits from low signal level cables.

Signal cables are usually manufactured using polyethylene which is adequate for normal use. Where high heat or

chemical action will attack poly cables, teflon (DuPont) dielectric and sheathed cables should be used, such as in aircraft or industrial plants. The National Fire Underwriters now requires non-fire supporting cable to be used for all open wiring in public buildings. Fire insurance rates could be greatly reduced in computer, nuclear accelerator and other large installations if TFE or FEP cables were used.

Coax Cable Connectors — Any connector must be able to interconnect with very low d.c. series resistance, something less than 10 milliohms. The impedence of a connector is usually of no consequence below approximately 300 MHz since the connector does not contribute to circuit performance until its length approaches 1/20th of a wavelength. For this reason, 50 Ω connectors can be attached to 75 Ω **video** cables with no detrimental effect. Above 300 MHz, coax connectors should be impedance matched to the system impedance.

There are many types and series of coax connectors presently available, and the multiplicity is probably very confusing to most users. Many of the lesser known series were designed for specific problem solutions or were developed by commercial companies for their own proprietary product line. Through the years, the connector series listed below have gained universal acceptance due to their simplicity and outstanding performance. They are produced and stocked by a majority of coax connector manufacturers.

Nominal Cable Size O.D.	Connector Size	Quick Disconnect	Threaded
.3 to .425″	Standard	C	N
.10 to .300″	Miniature	BNC	TNC
.10 to .242″	Subminiature	TPS	TCM

Much can be written to discuss the advantages of one series of connectors over another and usually the choice is either economic or performance depending upon the required system parameters. This discussion is outside the intended purpose of this paper; however, a mention should be made of the cable to connector attachment philosophy concerning crimping or soldering.

Crimping is normally used where speed of attachment is important or where it is virtually impossible to solder due to lack of available soldering iron power as on the top of a telephone pole or in a cable vault. Crimping requires an expensive crimp tool that can be improperly used or out of adjustment to give a poor connection. Additionally, crimped contacts over a period of time usually corrode, making for a bad contact particularly in chemical or salt atmosphere. Soldering on the other hand does not require any expensive tools not normally found in any tool box. The soldered connection will not corrode provided adequate heat is applied and correctly done to avoid a "cold solder joint." One of the advantages of the solder approach is that many coax connectors are now made to be used over and over again with no special tools and no replacement parts required. This is particularly advantageous in shipboard or field locations where special parts or tools are not always available.

2. Noise

Electrical noise has the accepted definition of being any unwanted and interfering voltage developed within, or external to a system, which reduces the performance of that system. Interfering noise has always been a problem and in the past was usually reduced by brute force filtering, which worked on the principle of stopping the noise **after** it had entered the system. This method was quite expensive, but reasonably effective since signal information voltages were low in frequency while systems were few and not too large or complex.

Present day communication and data systems are continually becoming larger and more numerous, using higher information rates and frequencies, in an atmosphere of expanded electrical and electronic equipment usage. The net result is ever increasing interference and noise creating an electronic traffic jam of major proportions. This applies equally whether low level analog or digital pulse systems are used. Filtering is practically useless or, in some cases, completely unusable since it produces excessive deterioration of the desired pulse waveforms, or inaccuracies and distortion of analog signal voltages. Obviously, noise reduction is best accomplished by simply stopping the noise **before** it enters the system. This discussion describes how external noise is introduced into systems by the **equipment interconnecting wiring, and the improvements that can be realized by installing** noise rejecting type cables, while applying good equipment isolation and grounding techniques.

Most electronic equipments do not produce random noise unto themselves and usually perform the singular task they were designed to do. When assembled and connected to other equipments to form a system, unwanted noise is picked up **by the interconnecting wiring** through the direct contact action of ground loops and common mode returns, or by inductive and capacitive pickup of nearby radiated fields. A desired signal in one circuit can be noise to another, and could be produced by local circuits within the system or from equipment completely removed and external to the system. Conversely, these same cables will **radiate** or **cross talk** the signal they are carrying into adjacent circuits becoming themselves a **generator** of interference to other data systems, or the cause of security compromises in classified military communications. This action is further compounded by poor cable to equipment **impedance matching** which produces signal reflections and high standing wave ratios. In other words, **poorly selected and installed** cabling can act as both noise transmitting and receiving antenna or as undesired primary and secondary windings of coupling transformers, placing interference where it should not be.

Systems are often designed, fabricated, and installed using the simplest multiwire cable or grounded coax between equipment, racks, and buildings, not realizing that they will probably encounter and pick up all manner of interference. Nearby electrical equipment such as high power radar, broadcast stations, power distribution mains, fluorescent lighting, arcing motors, teletype, and communications cir-

cuits are but a few of the noisemakers. The lower the system signal voltage level, the greater is the susceptibility to this outside interference.

A newly designed system might work fine on paper or when first assembled for checkout, but when installed at its final crowded location on ship or shore, just will not perform as anticipated. Only then is it realized that the complete system has picked up much noise and hum, or is itself radiating so heavily, that the equipment is unusuable.

Costly additional effort, parts, and time must be expended to locate and attempt to eliminate the causes of the noise pickup, sometimes with little success. To avoid this unnecessary waste, cable to equipment interface engineering should be applied at the **start** of system planning and design. This applies to all systems irrespective of whether the signal is low or high frequency, or used in TV, telemetry, timing, ordnance, environmental testing, computer, telephone, test instrumentation, or just plain communications. Each system must be considered individually, since the signal frequencies and amplitudes **within the system** as well as the anticipated external interference will dictate what type of cabling and installation techniques are to be used.

Following are typical examples where good cable engineering is being applied. Low-level **environmental** systems predominantly now use "guarded" balanced and shielded lines to transmit the calibrated transducer test voltage to an isolated charge amplifier. **TV video is distributed over** 124-ohm "shielded twisted pair" or twinax, instead of coax, in high noise areas to obtain the low frequency magnetic field cross talk and hum cancellation provided by the "twist". Digital engineers in the **computer** and **instrumentation** fields must use good high-frequency design engineering to transmit nanosecond rise time pulses. A 10-nanosecond rise time pulse is equivalent to 100 megahertz RF and must be transmitted using the best coax cable techniques to avoid pulse reflection, false noise triggering or data inaccuracy. Special care will be required to keep noise from entering information systems, particularly aircraft. Low level communication circuits and cabling should be space separated and have effective shielding from adjacent parallel power circuits to avoid induced hum. Unprotected circuits, such as ordnance and timing, can receive false pulsing if exposed to external radiated RF interfering fields. High megawat pulsed radar will introduce both its carrier and PRF into nearby sensitive low-level unprotected cable runs acting as receiving antennas. Sometimes the transmitted pulses have amplitudes of hundreds of thousands of volts, as used in **atomic energy testing** or linear accelerators, thereby producing large magnetic and capacitive interference fields. These in turn play havoc with local cable connected instrumentation and electronic equipment.

In the case of nuclear attack, a tremendous electrical field will be transmitted many miles from ground zero to induce extremely high voltages in all unguarded and unprotected cable and equipment, with the resultant burnout of all sensitive components. Solid-state transistors and diodes, integrated circuits, front end R.F. coils, sensitive relays and reeds are typical of the sophisticated elements used today for both military and commercial systems that will fail even though far removed **from** the fireball area. It is estimated that a vertical electrical field intensity of 50K volts per meter will be present 62.5 miles from a 10-megaton explosion near the ground.

In today's economy, the lack of money, time and qualified personnel will not permit the very complicated and costly post-completion interference cleanup of poorly engineered systems. Expensive electronic equipment handling low-level signals cannot be interconnected with cables and connectors and still be expected to work properly in a system. The use of coax, twinax, triax, or double shielded balanced line, "quadrax," in isolated or guarded circuitry, will do much to suppress outgoing EMI and RFI while reducing incoming unwanted noise pickup.

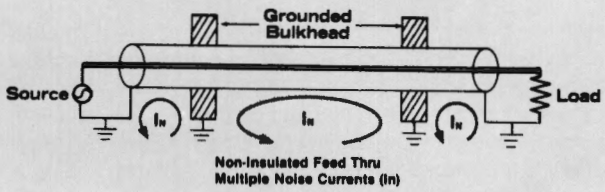
This protects both your system and the adjacent system from mutual interference. Obviously, careful cable to equipment interface planning must be exercised in the future to produce workable compatible systems, and design engineers will not be free to treat cable installation casually as in the past.

COAX CABLE

In all cases of potential interference, low or high frequency, shielded cable should be used to protect against magnetic and capacitive stray fields. Grounded coax cable installations are excellent and can be used from 20 KHz to 5 GHz for most systems. But even coax, if subjected to very strong interference will not completely protect the desired signal. Then, more sophisticated cable and equipment isolation techniques must be used dependent upon the frequency of the interfering noise and how it enters the cable system. What additional measures are taken to reduce noise will conversely reduce outgoing radiation and cross talk.

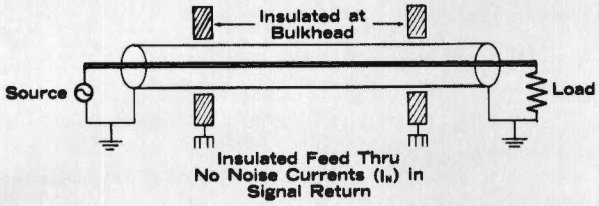
GROUND LOOPS AND COMMON MODE RETURNS

Coax cable consists of an inner and an outer conductor insulated from each other, with both conductors carrying the desired signal currents (source to load and return). Inas-much as the outer conductor is usually grounded at the source, load, bulkheads and other intermediate points, "ground loop" or "common mode" currents caused by potential differences of external noise sources are also carried on the outer conductor.



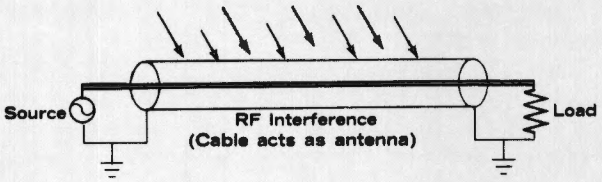
Non-Insulated Feed Thru
Multiple Noise Currents (In)

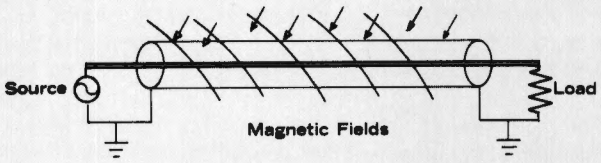
Since the desired signal and the undesired noise are both carried on the same outer conductor simultaneously, noise will be introduced into the system, greatly reducing the "signal-to-noise ratio." Low frequency signals (20 KHz to 6 MHz) are particularly susceptible to both ground loop and common mode interference. In this case, coax cable is recommended with the complete coax chain having a **minimum** number of outer conductor ground contacts. Reducing the number of ground connections reduces the number of possible ground loops. This demands that major equipment, relays, switches, connectors, patch panels, etc., be **isolated from ground** with the ultimate being one system ground connection at the source.



RADIATED FIELDS

Where strong radiated noise fields exist, such as high-powered radar, broadcast stations, power lines, fluorescent lighting, office and industrial machinery, multiple cable runs, etc., the cable conductors act as receiving antennas or secondary windings of transformers and pickup the external noise sources.

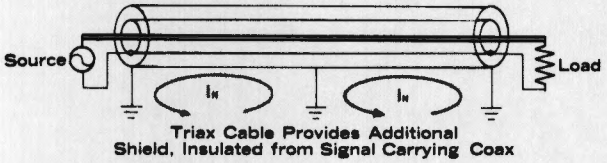




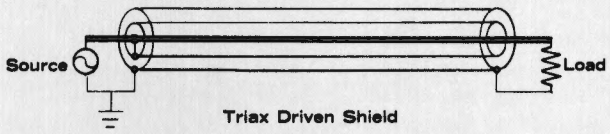
A particularly bad source of noise pickup is the "cross talk" or induced currents encountered in large multiple cable installations.

To protect against these radiated noise sources, two types of improved cable are used:

(1) TRIAX CABLE — Triax is coax cable with an **additional outer copper braid** insulated from the signal carrying conductors that acts as a true shield and protects the enclosed coax conductors. This braid or shield is grounded and bypasses both ground **loop** and **capacitive field** noise currents away from the signal carrying coax, thereby greatly improving the "signal to noise" ratio over the standard coax cable usage.

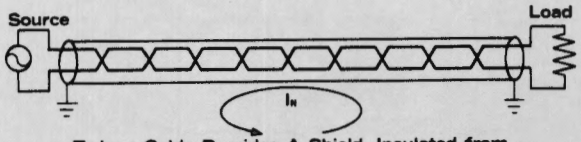


Triax cable is also used in "Driven Shield" applications where the inner conductor and first braid are driven in parallel at the transmitting end and work against the outer braid which is insulated above ground. At the receiving end, the inner braid is left floating, providing a "Faraday" shield between the inner conductor and outer braid. In this way the cable **distributed capacitance** is greatly reduced, thereby reducing cable losses and loading. This application is most effective in hi frequency transducer data systems where the distributed capacity in coax cable limits the data accuracy. (Page 129, Reference No. 1). Still another use for triax is to use only the two outer braids as a low impedance transmission line (approximately 12 ohms) which can be used to carry high-current pulses to low impedance laser lamps or exploding bridge wire (EBW) ordnance systems. Triax cable and connectors completely **insulated** from the ground are available for these applications.



(2) TWINAX CABLE — Twinax cable is a two-conductor twisted balanced wire line having a **specific impedance** with a shielding braid around both wires. Twisting the two balanced signal carrying wires provides cancellation of any random induced noise voltage pickup, thereby giving protection against **magnetic** noise field of the low-frequency variety that passes through the copper braid. **Trompeter twinax cable increases this protection many fold by simply inserting (2) plastic fillers under the braid. The braid is thus pushed away from the signal pair thereby lowering the leakage capacitance to ground with an attendant lowering of cable losses. Additionally, by using more copper wire in the braid and weaving it tighter, the coverage is improved to 90%.** This cable also provides protection against ground loops and capacitive fields, as did triax cable. Twinax cable

usefulness, however, is limited to approximately 15 MHz since it has rather high transmission losses above this frequency. 124 ohm twinax is extensively used by the Bell Telephone System for TV video transmission. Twinax cable and concentric connectors are available for low frequency, digital and video distribution systems. (Pages 5-47 Reference No. 1).

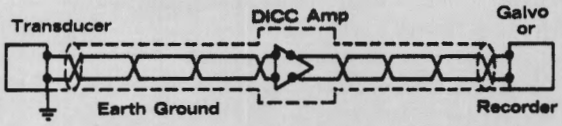


Twinax Cable Provides A Shield, Insulated from The Twisted Pair Signal Carrying Conductors

GUARDED TWINAX CABLE HOOKUP

(Chapter 4 and 6 Reference No. 4)

Additional **common mode rejection** of noise can be obtained in instrumentation systems, where thermocouple and other transducer information must be remotely recorded, by using twinax with only one ground contact located at the transducer. **Insulated** concentric twinax connectors are available.

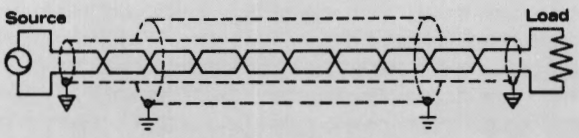


Guarded Twinax Cable System (one ground)

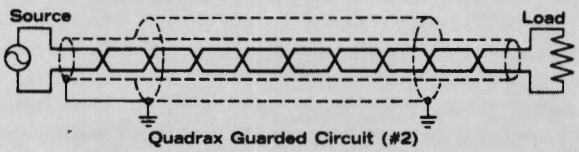
QUADRAX GUARDED CIRCUIT

(Page 77, Paragraph 6.11 Reference No. 4)

For the ultimate in flexible cable protected and guarded circuits, twinax cable with **two** separate and insulated braids (quadrax) can be used wherein the two braids are connected to "system" ground and "earth" ground, respectively



Quadrax Guarded Circuit (#1)



Quadrax Guarded Circuit (#2)

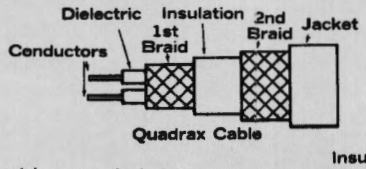
Quadrax cable can also be used to provide additional noise and EMI suppression by connecting both shielding braids earth ground at one place if a separate equipment ground is not available. The inner braid is left floating above ground at all other locations to act as a Faraday shield and provide additional circuit isolation. Coax cable with **two** extra and insulated braids can be used in similar engineering concepts for unbalanced systems.

BONDING AND GROUNDING

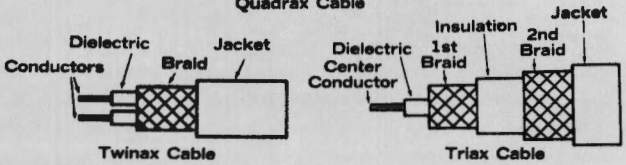
Good bonding and grounding are absolutely essential also if noise pickup reduction is to be accomplished. Much has been written to define the correct methods to accomplish both with some suggested reading material being listed in the bibliography. It is desired to point out here that equipment isolation cabling, bonding, and grounding are all part of the noise pickup and EMI/RFI problem.

Following are common conditions that require detailed consideration:

1. "Earth" grounds require extensive grids, ground rods, and chemical preparation to obtain an extremely low resistance and impedance system ground return.
2. Where equipments comprising a low frequency data system are widely separated, equipment ground "planes" in many instances should be isolated from earth grounds to avoid "noisy" ground loops caused by power and other equipment in the immediate area.
3. If parallel cabling is necessary, space isolate cabling of similar functions, i.e., R.F. from R.F., video from video, and cables carrying vastly different voltage levels so that they do not have mutual capacitive or inductive coupling.
4. Properly terminate all pulse and high frequency cables in their characteristic impedance so that the cable reactive components are cancelled out and the voltage standing waves are reduced to a minimum.
5. Select the proper cable for the job. The higher the frequency, the faster the pulse rise time, or the longer the cable run, the bigger the cable must be to reduce dielectric losses and lessen the distortion of pulse shapes.
6. If "system" ground and "earth" ground must be connected, it should be done at minimal locations (preferably one) using extremely low-impedance bonding paths and materials. On the other hand, R.F. and high frequency bonding should be made quite frequently to provide the shortest R.F. path to ground and prevent the ground return from acting as an addtional length of antenna. **To repeat, the method of equipment interconnecting and grounding is a function of the signal frequency (L.F., video or R.F.), and no one simple answer can be provided.**



Quadrax Cable



Twinax Cable
Triax Cable

SYSTEMS USAGE

Most engineers are quite familiar with the long time use of 75 ohm coax cable used in I.F. and baseband telephone transmission installations and the universal use of the same cable for broadcast and cable TV. More recently, with the rapid growth of commercial computer data distribution, coax and twinax cables are being used for local dedicated installations. Even newer are the non-dedicated commercial coax **data bus** systems, such as Ethernet and Z Net, where many terminals are tied to one high bit-rate trunk cable. Military aircraft systems are now being designed calling for 78 ohm twinax data bus distribution for main functions of guidance and control, navigation, communications, etc. per MIL-STD-1553B using the TRS and TRB series connectors. (See table). MIL-STD-1397 specifies 75 ohm triax in naval ship digital data bus applications which use the TRB and TRC series connectors listed in MIL-C-49142.

As previously discussed, high bit-rate signals require high-frequency transmission cables (coax, twinax, triax and even quadrax) to minimize amplitude and frequency distortion and to prevent pick-up of noise from external interference. It is incumbent upon the design engineer to select the optimum cable and connectors for maximum reduction of interference due to radiated R.F. and magnetically coupled or direct contact ground loop noise in his application. This can result in reducing the number of noise suppression filters and amplifiers required. A repeated word of caution is offered here for those contemplating digital use. Low voltage digital lines should not be placed in the near proximity of high voltage and high current cables nor should a single multi function connector be used due to the strong probability of cross-talk coupled interference. Physical separation of the cables is the first and best solution, with shielding and isolation above ground the second consideration.

The choice of cable type and its installation is defined generally as follows:

1. Grounded Coax: Can pass the high information rates but is subject to ground loops as well as magnetic and radiated noise pickup.

2. Ungrounded Coax: Same as (1) but substantially lowers the ground loop interference.

3. Triax Cable: Same as (2) and additionally removes the radiated noise, but does not reduce magnetic interference.

4. Twinax Cable: Passes only medium information rates, but additionally hinders the pickup of magnetic interference due to the "twist" of the signal pair. (Equipment usually operated with balanced inputs and outputs.).

5. Quadrax Cable: Same as (4) but gives double radiated noise protection and allows the inner braid to be used for d.c. control voltages in some applications.

6. Ungrounded versions (3) and (4) provide even more ground loop isolation.

The choice of materials to be used in these cables is of major importance. For commercial installations in public buildings, National Electrical Code, Underwriters Lab and local ordinance requirements must be complied with. Fire wicking cables routed horizontally thru fire walls and vertically floor to floor are required to be metal ducted — a very expensive and inflexible mode of construction. Approved cables made of FEP can be routed horizontally, without ducting, in air plenums with a great reduction in size and cost and with much greater flexibility for future modifications. Increasing insurance premiums will almost dictate that flame retardant materials be used in all future public building cable installations to reduce potential loss of life and property. The same applies to military aircraft cables which must be able to additionally withstand exposure to fuel and cleaning solvents. Connectors are available for these special cables.

An interesting point might be discussed here concerning RG59, RG62 and other coax cables using copperweld wire for the center conductor. Copperweld is a high resistance steel wire with a copper cladding on the outside and was originally intended to give strength to TV cables when suspended from poles or when pulled thru ducts. This steel wire will increase the cable attenuation on a long length run particularly at the lower frequencies due to the high resistance of the copper cladded steel. RG59 and RG62 have approximately 44 ohms per 1000 loop feet, as against 17 ohms when using pure copper for the same size center conductor. It is also difficult to effectively crimp the center contact pin on the hard steel copperweld wire.

Concerning the outer conductor or coax cables, a copper braid coverage of 80% should be minimum with 90% or over being preferred. Many manufacturers skimp on the quantity of copper wire braid used thereby affecting its loop resistance, line and transfer impedance. A good "rule of thumb" is — if the dielectric is visible through the braid (without bending the cable) the cable should not be used.

Where greater **mechanical** protection is required against vandalism, sabotage, rough handling, rodents, fire or other high risk conditions, armor covering can, and should be applied over the delicate cables. The coax cable VSWR quickly deteriorates if repeatedly stepped on or bent beyond its tolerable radius of bend. Mines, prisons, open field use, sewers and engine compartments are just a few areas where armoring should be considered.

Trompeter Electronics offers many connectors, cable assemblies, patch panels, and some passive switching equipment to complete the installations (1) thru (6) described previously. The connectors are available in various sizes with bayonet or threaded coupling, solder or crimp cable affixment as options. Listed below are the letter and numerical series designations for each cable and connector combination. Each connector series offers plugs, bulkhead jacks, cable jacks, tee's, attenuators, etc. Complete cable assemblies can be fabricated to customer's order by designating type and length of cable, and connectors on each end.

CONNECTOR TYPE	LETTER DESIGNATION		NUMERICAL SERIES DESIGNATION (PL, BJ, CJ, ETC.)
	BAYONET	THREADED	
SUBMINIATURE COAX	TPS [1]	TCM [2]	50 350
SUBMINIATURE TWINAX/TRIAX [3]	TRS [2,4]	TTM [2]	150 3150
MINIATURE COAX	BNC [1]	TNC [1]	20 40
MINIATURE TWINAX/TRIAX	TRB [1,4,5]	TRT [2]	70 370
STANDARD COAX	C [1]	N [1]	90 95
STANDARD TWINAX/TRIAX	TRC [1,5]	TRN [5]	80 380
QUADRAX	QRC [2]		100

The older, but not recommended for new systems, 2 pin twinax connectors meeting MIL-C-3655 are also supplied by TEI as follows:

MINIATURE TWINAX, PIN AND SOCKET ADJACENT, STEPPED DIELECTRIC	TWBNC [1]	TWTNC [1]	30 330

NOTES: [1] EXISTING GOVERNMENT DESIGNATION
[2] TEI DESIGNATION
[3] Available in 3 and 4 lug configuration for separation of redundant circuits.
[4] MIL-STD-1553B Usage
[5] MIL-STD-1397 Usage (MIL-C-49142)

COMPONENTS AND EQUIPMENT AVAILABLE

Trompeter Electronics is primarily concerned with supplying cable and connectors necessary to provide protection for low or high frequency systems. This includes coax, triax, twinax and quadrax cables, connectors and patch panels. The catalog lists standard system hardware available to accomplish specific tasks. Our technical staff is available to assist in selection of these components and to help in providing any components not shown.

This discussion was not intended to be a full text, but to give some insight into what must be done to produce noise free systems without extensive rework and debugging. Many comprehensive and enlightening articles and books have been written, a few being listed below. They in turn list other references that should be studied for more detailed information. Reference (1), (2) and (4) are readily available from the publishers.

INTRODUCTION

The panels shown on pages 10, 11, 20, 21 are standard size. However, special panels of any size and jack configuration can be furnished on special order. The panels shown will accept all jacks shown on pages 12, 13, 15 and 33, except as noted. Panels containing 'D' and 'DD' holes for standard bulkhead jacks are shown on pages 20 and 21. For high density panels with 50 ohm subminiature jacks, refer to page 16. Western Electric panels with 75 ohm subminiature jacks are shown on page 18.

ORDERING INFORMATION

Panels and jacks are selected separately and combined for one part number. Ordering information for 'D' and 'DD' panels is contained in the tables pages 20 and 21.

JS - 12 / J3

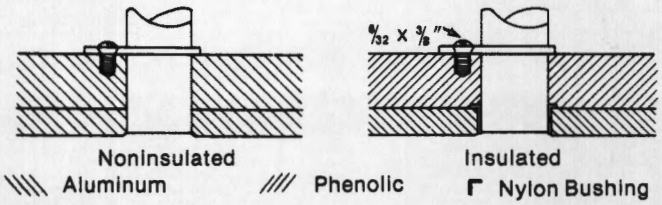
Select jack type (pages 12, 13, 33)
JS = Aluminum panel (open notch)
JSI = Insulated panel (open notch)

PANEL CROSS SECTION



PANEL SPECIFICATIONS

SIZES: All panels are 19" wide by 1¾" or 3½" high by 9/16" thick. Standard construction consists of 3/16" aluminum panel and a 3/8" aluminum or phenolic (if insulated) back bar. Vertical hole spacing is .625" unless otherwise noted, and horizontal hole spacing is as shown on each panel. All double row 3½" panels can be supplied in W configuration, i.e. 1" vertical hole spacing.

NOTCHING: In accordance with MIL-STD-189. Closed notching is available on special order.

FINISH: Standard color is FED-STD-595-26307 (light gray). Special paint finishes and colors are also available on special order. Customer must furnish FED-STD-595 number or a paint chip.

MATERIAL: JS Series — Common ground panels. Panel and backbar are both aluminum grade 6061-T6. JSI Series — Insulated panels. Panel is aluminum grade 6061-T6 and backbar is XXX non-hydroscopic phenolic. Nylon sleeves insulate the jacks from the panel. Insulated panels are recommended where ground loops are to be avoided.

IDENTIFICATION: Each panel is normally equipped with one or more ½" x 16½" (card size) stainless designation strips (DS1) with card and plastic window. High density panels are normally supplied with one or more ¼" x 16½" (card size) stainless designation strips (DS4). Panels normally supplied with ½" designation strips can be supplied with ¾" x 16½" (card size) stainless designation strips (DS2).

MARKING: Panels may be engraved or silk screened in lieu of or in addition to designation strips, thus permitting customizing of the panel. Patch jack locations can also be marked in the rear of the panel for easy location of jacks from the back of the rack. These markings are usually stenciled.

Standard Patch Panels

JSI-56
Accepts all jacks except J4 and J9 series.

See Pages 12, 13, 15 and 33 for appropriate jacks. Note exceptions.

Standard Patch Jacks

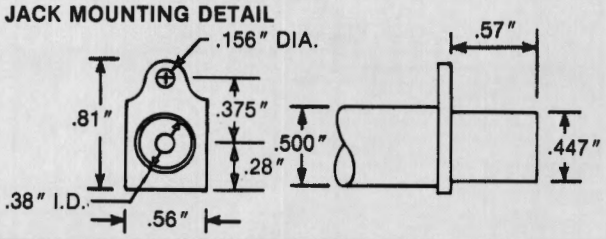
Coax

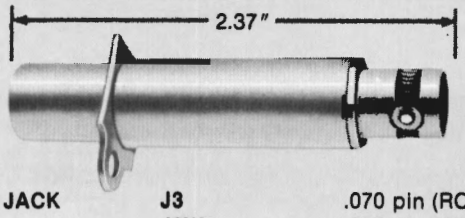
INTRODUCTION

The pictured jacks provide the maximum flexibility to route signals from one place to another. They are used in shielded wire, video, and R.F. applications, and will mount on patch panels illustrated on pages 10 and 11. The jacks can be intermixed on the same panels providing mechanical limitations are recognized.

Also, coax jacks shown are available in two standards differing in the size of the center contact pin — Western Electric is .090″ (75 ohm); RCA is .070″ (50 ohm). It should be noted that Western Electric type jacks must be used only with Western Electric type patch cords and conversely, RCA type jacks must be used only with RCA type patch cords.

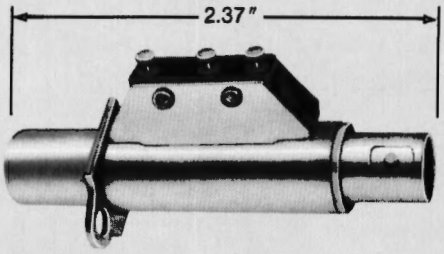
JACK MOUNTING DETAIL





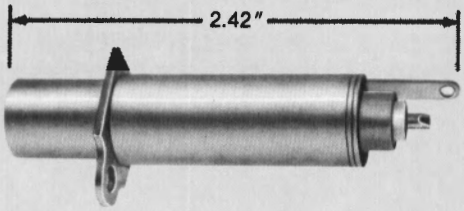
PATCH JACK (BNC)	**J3**	.070 pin (RCA)
	J3W	.090 pin (WE)

Rear mates with Trompeter PL20-N series or any standard BNC plug.

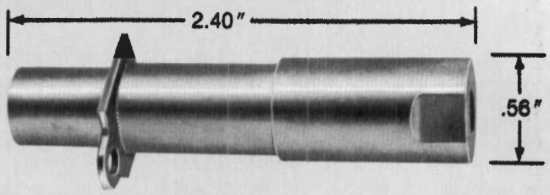


PATCH JACK (BNC) (Microswitch)	**J3A**	.070 pin (RCA)
	J3WA	.090 pin (WE)

J3 with external SPDT microswitch activated by insertion of patch plug. Microswitch may be added to all coax jacks. To designate add the letter A to the part number.

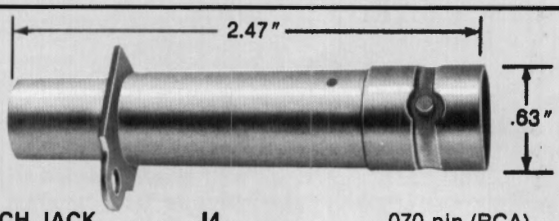


PATCH JACK (Solderpot)	**J3D**	.070 pin (RCA)
	J3WD	.090 pin (WE)



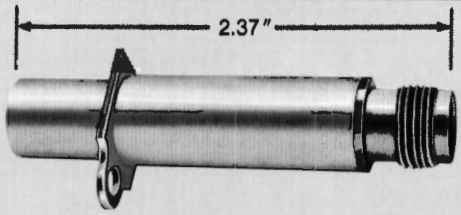
PATCH JACK (Cable entry)	**J3E-N ***	.070 pin (RCA)
	J3WE-N *	.090 pin (WE)

Usable whenever cable entry is desired in place of standard connectors.



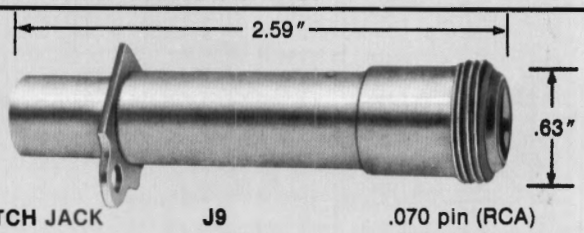
PATCH JACK (C)	**J4**	.070 pin (RCA)
	J4W	.090 pin (WE)

Rear mates with any type "C" plug. Usable on JS/JSI 12, 14, 16, 20, 24W and 40W panels only.



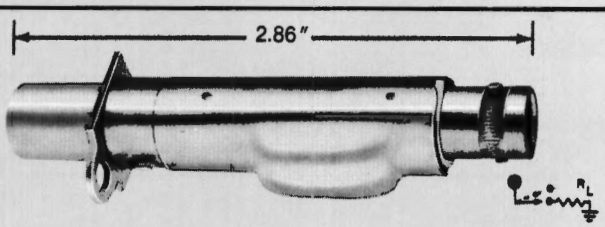
PATCH JACK (TNC)	**J5**	.070 pin (RCA)
	J5W	.090 pin (WE)

Rear mates with Trompeter TNC plug, PL40-N series or any standard TNC plug. Usable on all panels when using PL40-N series or other reduced O.D. TNC.



PATCH JACK (N)	**J9**	.070 pin (RCA)
	J9W	.090 pin (WE)

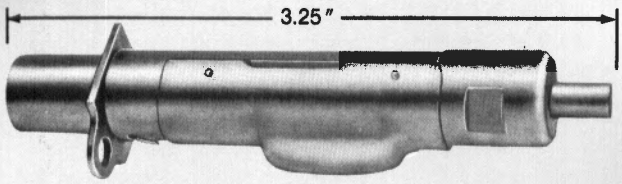
Rear mates with any type "N" plug. Usable on JS/JSI 12, 14, 16, 20, 24W and 40W panels only.



PATCH JACK (BNC) (Self-terminating)	**J13-R ***	.070 pin (RCA)
	J13W-R *	.090 pin (WE)

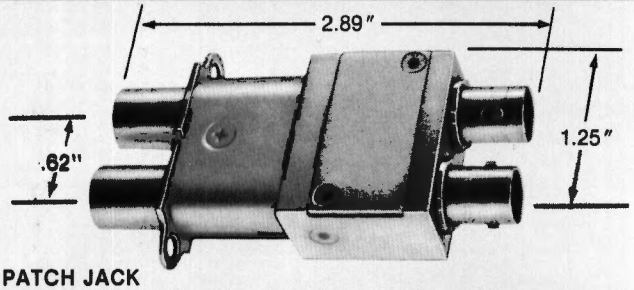
Rear mates with any BNC plug. Circuit is terminated when patch plug is removed. Signal degradation increases when used above 100 MHz.

* Substitute cable group number for N - Page 30. Substitute resistance for R (½ W 5%).



PATCH JACK (Crimp)	**J13C-N-R ***	.070 pin (RCA)
(Self-terminating)	**J13WC-N-N-R ***	.090 pin (WE)

Same as J13-R except that crimp type cable entry is used. Use cable table on Page 27.



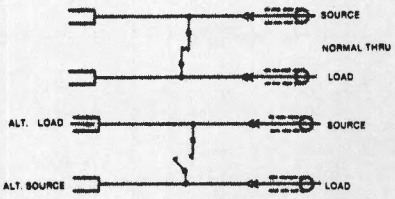
PATCH JACK
(Normal Thru) **J14 Series**

The J14 series is a dual coax jack which automatically provides a "normal thru" signal path without the use of looping plugs or patch cords. The normalling switch contacts utilize a unique self-wiping action for positive contact.

Standard, terminated and monitor types, with schematics, are shown below. M is monitor, T is terminated. Jacks are normally furnished with BNC (UG1094 type) connectors. Signal degradation occurs when used at frequencies above 100 MHz.

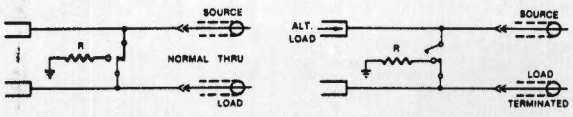
Tabs are normally back to back (as shown). However, they can be supplied side by side for horizontal mounting on special order. Add L to part number for left hand tabs and R for right hand tabs. (Example: J14WL).

STANDARD	**J14**	.070 pin (RCA)
	J14W	.090 pin (WE)



The standard J14 or J14W is used to provide a pair of jacks with a normal through circuit without the use of looping plugs or patch cords. A plug inserted into either jack breaks the normal through. Each jack provides a wiping action for positive contact.

TERMINATED	**J14T-R ***	.070 pin (RCA)
	J14WT-R *	.090 pin (WE)

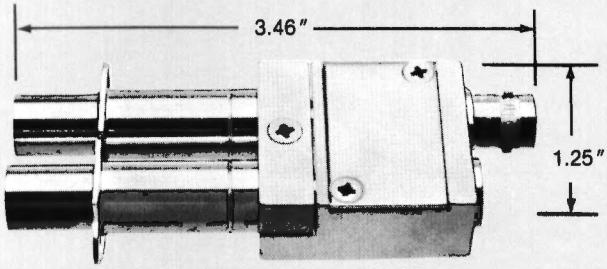


The terminated version is used to provide a resistive load to the unused side. A plug inserted into the source side automatically terminates the load side. Conversely, a plug inserted into the load side automatically terminates the source side.

MONITOR	**J14M**	.070 pin (RCA)
	J14WM	.090 pin (WE)

The monitor version provides for monitoring the signal without breaking the normal through by inserting a plug on the monitor side. A terminated version is also available. When a plug is inserted in the load side the source is automatically terminated. This version is a J14MT-R or J14WMT-R. Again substitute resistance value for R.

A single pole double throw switch can be added to the J14 or J14W only. The designation for this type of jack is J14A or J14WA.

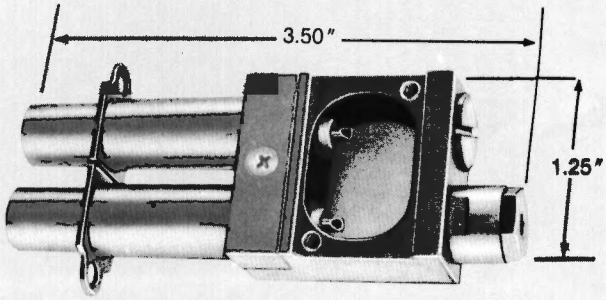


PATCH JACK (Dual) — Wired

J15B (BNC)	**J15H (TNC)**	.070 pin (RCA)
J15WB (BNC)	**J15WH (TNC)**	.090 pin (WE)

PATCH JACK (Dual) — No Wiring

J15BA (BNC)	**J15HA (TNC)**	.070 pin (RCA)
J15WBA (BNC)	**J15WHA (TNC)**	.090 pin (WE)



PATCH JACK	**J15-N ***	.070 pin (RCA)
(Dual)	**J15W-N ***	.090 pin (WE)

Substitute cable group number for N. See page 30. Dual coax jack with provision for one or two cable entries. Normally supplied with one standard cable entry connection.

These dual jacks may be mounted vertically or horizontally on ⅝″ centers. Tabs are normally back to back (as shown). However, they can be supplied side by side for horizontal mounting by adding L to part number for left hand tabs and R for right hand tabs. (Example: J15B-L).

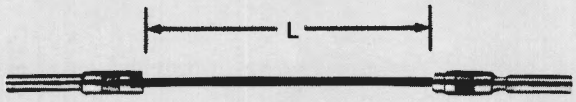
* Substitute cable group number for N - Page 30. Substitute resistance for R (½ W 5%).

Standard Patch Cords and Plugs

Coax

Trompeter has established facilities and techniques to manufacture coax patch cord and cable assemblies rapidly and efficiently thus providing the customer with definite quality and cost advantages. Standard lengths 6″, 12″, 18″, 24″ and 36″.

It should be noted that RCA .070 patch cords ARE NOT interchangeable with Western Electric .090 patch cords. Standard patch cords are made from RG58/U (50 ohm), RG59/U (75 ohm) and RG62/U (93 ohm) coax cable. Modifications of most items to provide special capabilities may be supplied on special order.



PATCH CORD

PC-L-Z *	(50, 75, 93 ohm)	.070 pin (RCA)
PCW-L-Z *	(50, 75, 93 ohm)	.090 pin (WE)

Miniature Patching 50 Ohm

Coax

INTRODUCTION

Trompeter patch panels that accept J8 and J8D miniature jacks are for use in high density 50 ohm patching. These panels are 19″ long and have vertical and horizontal hole spacing ½″ center to center unless otherwise indicated. Panel holes are tapped $\frac{5}{16}$-32-2B. Noninsulated panels are aluminum grade 6061-T6, insulated panels are phenolic. Both have stiffener bars.

Western Electric type miniature 75 ohm patching, shown on pages 18 and 19, is not interchangeable with this series.

Miniature 75 Ohm Coax

INTRODUCTION

A complete family of Western Electric type miniature panels, jacks, connectors, plugs, patch cords and looping plugs have been designed for high density low VSWR 75 ohm coaxial applications such as microwave, sub-carrier telephone or similar systems. The Trompeter designed J12 jack and PL11C plug combination have a VSWR of 1.04:1 when used in the 60-80 MHz range. The J12 is interchangeable with W.E. 560 jacks. Panels are supplied in insulated versions only for either rack or flush mount and are painted black. Other finishes are available. These items are NOT interchangeable with those items shown on pages 16 & 17.

* Substitute cable group number for N - Page 30. Substitute resistance for R (¼ W 5%).

Miniature 75 Ohm Coax

DUAL PATCH JACKS

TEI's recently developed J18 dual patch jack operates in the same manner as the J14 in the Standard patch series (page 13). Load and source circuits can be reconfigured from "normal thru" interconnections to any cross patching desired. Additionally, in the J18T-R* jacks, patched out sources and loads are automatically switched "break before make" and terminated into a specified resistance.

Tabs for both the J15MW and the J18 group of dual patch jacks are normally back to back. However, they can be supplied side by side for horizontal mounting by adding an "L" to part numbers for left hand tabs (orientation is from rear of patch jack) and "R" for right tabs (example: J15MWL-N).

COAXIAL CONNECTORS • WRENCH CRIMP

WITH FAST 3-PIECE ASSEMBLY — EXCEEDS REQUIREMENTS OF MIL-C-39012, CATEGORY "A" (FIELD SERVICEABLE AND REUSABLE WITH ORDINARY TOOLS).

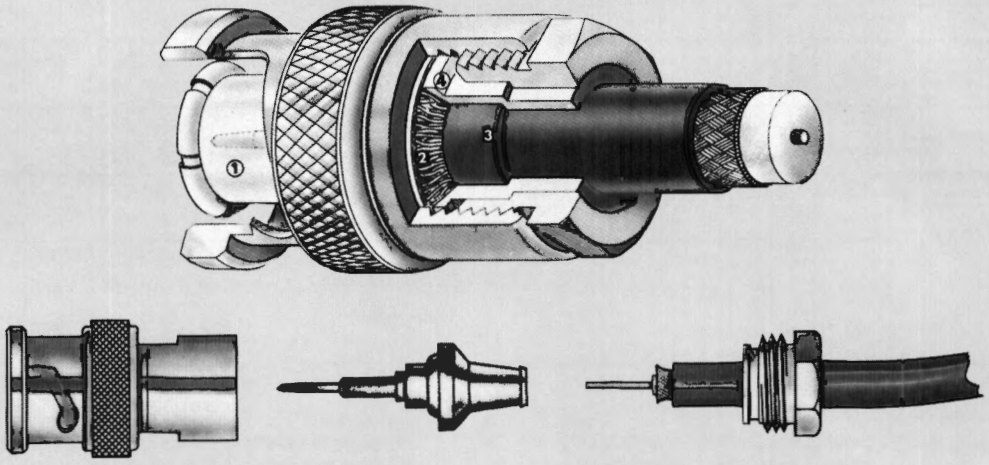
The old "UG" coax connectors required several cutting and stripping assembly operations, demanding precise and time-consuming steps to attach to the cable.

Most "crimp type" connectors require expensive tools for assembly and are not field repairable. The new WRENCH CRIMP provides an all new coax cable attachment method that crimps the outer braid (as well as retaining the jacket) using ordinary wrenching. A floating sleeve (4) permits clamping of braid without rotary movement. This method of clamping the braid is equally effective when using double braided cable such as RG223. It should be noted that there is no insulating material between the braid and the clamping surfaces (2). The connector features a (patented) heat treated beryllium copper outer conductor spring for positive electrical contact which is enclosed for improved EMI suppression (1). Other connectors use an open split spring usually made of brass. The connector additionally has a captive center contact that does not rely on the cable for positioning. Connectors are assembled and disassembled using ordinary tools and are usable over and over again.

The WRENCH CRIMP connector series uniquely holds TFE or similarly jacketed cable without the use of additional hardware. The connector-to-cable pull-to-destruct approaches the tear strength of the cable itself (3).

As an added feature, the center conductor pin for some Trompeter coax connector sizes can be crimped using Buchanan adjustable crimp tool No. 613439.

Certain connectors are standard in both 50 and 75 ohm. Specify the 75 ohm type by the prefix U.



INSTRUCTIONS FOR ASSEMBLY

Assembly instructions furnished by Trompeter are to be considered as a guide. Customers may wish to establish their own methods and techniques to suit their particular requirements.

1. Place "wrench crimp" nut onto cable.
2. Make a clean perpendicular cut through cable jacket, braid and dielectric, exposing 5/16" of center conductor.
3. Cut jacket back an additional 3/32" and bend braid outward to allow free entry of cone. This will prevent cone from forcing braid up under jacket.
4. Lightly tin center conductor.
5. Insert center conductor and dielectric into pin/cone assembly. Push edge of cone between dielectric and braid. Tapered cone will flare out braid and jacket. Continue to push cable into cone until cable dielectric seats against cone dielectric. The center conductor should be visible in pin solder hole. (Braid may be combed out over cone and excess strands trimmed to cone edge if preferred.)
6. Solder center conductor to pin.
7. Bring "wrench crimp" nut up onto tapered portion of cable.
8. Assemble connector body over pin/cone assembly and engage with clamp nut.
9. Wrench tighten to 30-40 in. lbs. torque.

Low VSWR Precision Patching 50 Ohm

INTRODUCTION

The increasing operating frequencies of modern communications and telemetry systems have created a growing need for precision patching equipment. Trompeter's 50 ohm low VSWR (1.11:1.0) patching system has been developed for these applications. This equipment is designed for use at frequencies up to 3 Ghz and at power levels up to 500 watts.

The J94 jack accepts an "N-series" male connector in back of the panel and the PL93-N and PL94-N patch plug at the front of the panel. J94 jacks may be panel mounted in Trompeter panels JSH-12, JSIH-12, JSH-24, and JSIH-24 as shown on page 20, or in a custom panel of your design.

The plugs incorporate a push-fit design that snaps into position in the jack and are available with or without a bayonet locking feature.

Normal jack spacing is 3 inches center to center. When patching adjacent jacks, the minimum bend radius of the cable must be considered. Trompeter standard patch cords made with Stancor 1000 will meet this requirement with a minimum length of 14 inches. In using any other cable, the minimum length must be 18 inches.

Full Die Crimp

BNC and TNC Series Miniature Coax

INTRODUCTION

Trompeter has designed a series of full die crimp plugs and jacks both BNC and TNC that are equivalent to MIL-C-39012B category D. A complete table for cable and tool data is provided. These connectors also come with a (patented) heat treated beryllium copper outer conductor spring for positive electrical contact for improved EMI/RFI suppression.

Wrench crimp and tool crimp cable groups are numbered separately due to the difference in fit requirements for the pin's wire cavity.

F Series, Miniature Coax

INTRODUCTION

Traditionally the F connector has been a low cost plier-crimp device utilizing the cable center conductor for a center contact. For those applications which require a more reliable termination, Trompeter has developed a line of F connectors incorporating the quality features previously described for the BNC line. These connectors are manufactured in the simple 3 piece *wrench* crimp configuration with gold plated **captive center contacts,** Teflon dielectrics and beryllium Copper female contacts. Cable connectors, shown here, will also accommodate the recently developed non-flammable FEP plenum coax cables manufactured by Hitemp, Phalo, Belden, ITT Suprenant, Times, etc.

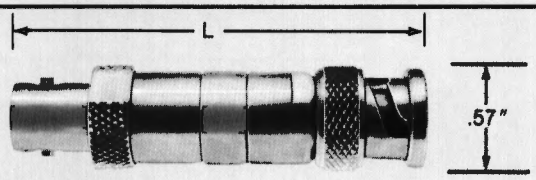
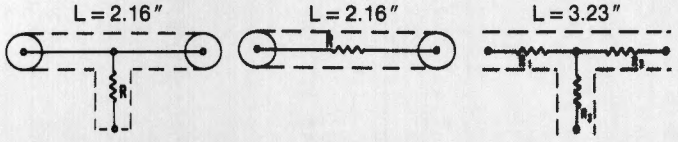
PATCH CORD HOLDER
CH50

10.75″ wide x 4.50″ deep

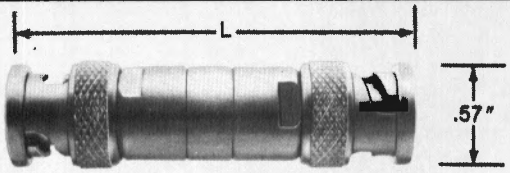
Black epoxy over steel wall mount for use with ¼″ dia. and smaller cables. Holds up to 50 cable assemblies.



BNC PADS
PART NO. (See Schematic) Max 10 MHz



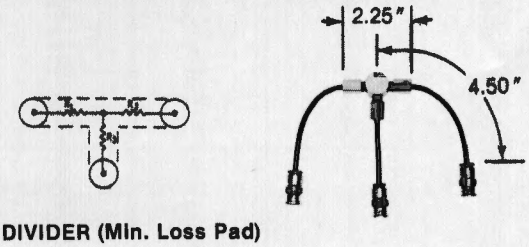
TNA2-R * **TNA3-R *** **TNA4-R's ***



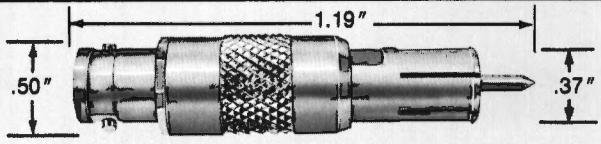
BNC ATTENUATOR (Video Frequency, Max 10 MHz)

TNA-Z-dB-BNC **	Male & Female	L = 3.24″
TNA-Z-dB-BNC/M **	Male Only (Shown)	L = 3.17″
TNA-Z-dB-BNC/F **	Female Only	L = 3.30″

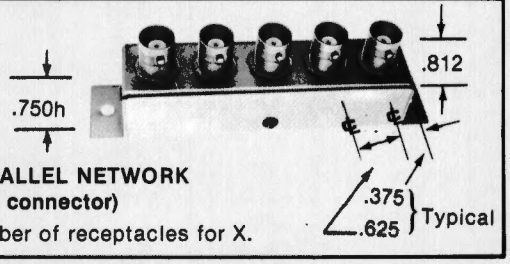
** Substitute impedance for Z, attenuation for dB.



POWER DIVIDER (Min. Loss Pad)
PD3-Z
Z = 50, 75, 93 ohm impedance. Max. 10 MHz.



PROBE PLUG FOR STANDARD PATCHING
MP4 .070″ pin (RCA) **MP4W** .090″ pin (WE)
Used to monitor J14 (Page 13) without interrupting normal thru signal.



MULTIPLE PARALLEL NETWORK
MPN-X (Type of connector)
Substitute number of receptacles for X.

* Substitute resistance value for R (½ W 5% standard, ¼ W & 1 W optional.)

TABLE 2: WRENCH CRIMP CONNECTOR - COAX CABLE

INTRODUCTION

Locate group number in top of columns. An X in any row-column intersection indicates a connector type available for this cable group. Substitute cable group number for N in appropriate part number. Example: Coax male connector for RG59 would be PL20-2. No X indicates a standard connector is not available, or available on special order only.

TWINAX-TRIAX-QUADRAX

Twinax-Triax-Quadrax Cables

INTRODUCTION

Twinax and triax concentric patching was designed to provide easy and quick connect and disconnect capability when using twinax and triax cables. These components are specifically for use where "Noise Free Guarded Systems" are required by MIL-C-49142. (See pages 2 thru 8).

The Trompeter twinax and triax components illustrated do not require mechanical alignment for mating and are available for use with cables of various sizes manufactured by Trompeter and other companies. All twinax/triax patch jacks will fit the patch panels shown on pages 10 and 11.

Twinax cable is a two-conductor twisted balanced line having a specific impedance, with a shielding braid around both conductors. The balanced twisted signal carrying wires provide cancellation of any random induced noise, voltage pickup or magnetic noise fields that pass through the copper braid. Twinax cable is used extensively in environmental laboratories, analog and digital signal transmission, T.V. video transmission, telephone applications and wherever signal frequencies below 10 MHz are distributed.

Coax cables in low-level signal applications are subject to pickup of noise through ground loop, magnetic fields and capacitive effects. Reduction of noise pickup and improvement of the signal-to-noise ratio can be attained by using "Triax" cable. Briefly, triax cable is coax cable with an additional outer copper braid insulated from signal carrying conductors. This additional braid or shield is grounded and bypasses both ground loop and capacitive field noise currents. The result is a better signal-to-noise ratio. Triax cable is used where very low-level and high-level R.F. signals are transmitted simultaneously through adjacent cables that are bunched together or in high energy fields from transmitters, radar and other noise generating devices.

Quadrax cables are similar to twinax cables with the exception that the quadrax contains one additional shield component. The balanced twisted signal pair with the two (2) separate insulated braided shields is used for the limitation of noise pickup or whenever the ultimate EMI suppression is required.

***By convention Blue goes to center pin.**

TRC Standard Twinax-Triax Series

INTRODUCTION

Trompeter designed "C" type concentric connectors are for use with the larger twinax or triax cables from .25" to .615" O.D. Each cable jack (CJ) will mate with each plug (PL) regardless of cable group. The "C" type triax/twinax connectors function the same as the 70 series illustrated on page 34 and feature a type of assembly requiring no special tools. This series meets the requirements of MIL-C-49142.

QRC Standard Concentric Quadrax Series

INTRODUCTION

Quadrax connectors were designed for the ultimate in protected and guarded circuit applications. Quadrax cable is a signal cable that has a balanced twisted pair of signal wires with two separate and insulated braids (refer to Noise in Cable Systems, pages 2 through 8). The connectors shown are concentric in design and do not require mechanical alignment for mating. They accept Trompeter Quadrax Cable Type QRC-78-2.

TWBNC Series Twinax Two-Pin Polarized

INTRODUCTION

The two-pin series of twinax connectors shown below are not recommended for new systems and should be considered for replacement purposes only. The concentric design is preferred since it does not require mechanical alignment for mating. MIL-STD-1553B permits designer discretion in selection of concentric design in lieu of two pin series. (Not to scale).

TRS Bayonet / TTM Threaded Subminiature Series

INTRODUCTION

Trompeter Electronics has developed a family of subminiature concentric twinax and triax connectors, jacks, plugs, and receptacles for high density installations which allows for an increase in packing density of up to 246%. They were specifically designed for Digital, Video Pair, Baseband circuits and where Noise Free Guarded circuits are required. These connectors are available in three lug, four lug and threaded versions for improved mechanical stability while providing error free redundant data bus capability.

TABLE 4: WRENCH CRIMP CONNECTOR - TWINAX/TRIAX/QUADRAX

INTRODUCTION

Locate part number in left hand column or cable group number across top, (obtain cable group number from table 3, page 38.) An x in any row-column intersection indicates a connector type available for this cable group. Substitute cable group number for N for appropriate part number. Example: male twinax connector for TWC-124-2 cable would be PL75-9. No x indicates a standard connector is not available or available only on special order.

The CD2-7 crimp die is similar to the die pictured on Page 26 and fits the CT2 crimp tool pictured on the same page. The Buchanan adjustable crimp tool, not shown, is additionally required for crimping the center plug pin and jack socket.

Wrench crimp and tool crimp cable groups are numbered separately due to the difference in fit requirements for the pin's wire cavity.

GENERAL SPECIFICATIONS

PANEL SPECIFICATIONS:

SIZES: 19″ wide, 3/16″ thick, 1 3/4″ (single row) or 3 1/2″ (double row) in height. Back bar 16 5/8″ wide, 3/8″ thick.

NOTCHING. In accordance with Mil-Std-189.

IDENTIFICATION: Each panel normally furnished with one or more 1/2″ x 16 1/2″ stainless steel designation strips (DS-1) with card and plastic window.

MARKING: Panels may be engraved or silk screened.

PLATING SPECIFICATIONS: TFS-1 (Letter)

A. .0001 Bright Nickel per QQ-N-290, Class 1 (over)
.000080 Bright Copper per Mil-C-14550, Class 5 (over)
.0005 max Electroless Nickel per Mil-C-26074A, Class 1 (3)

B. Except as specified in note (1):
.00002 Bright Gold per Mil-G-45204, Type II, Grade C, Class 00 (over)
.000050 Bright Nickel per QQ-N-290, Class 2 (2) (over)
.000080 Bright Copper per Mil-C-14550 (2)

D. .0001 Electroless Nickel per Mil-C-26074A, Class 1

E. .0002 Bright Electro Tin per Mil-T-10727, Type 1 and solder test per Para. 4531.

F. .00002 Bright Gold per Mil-G-45204, Type II, Grade C, Class 00 (4) (over)
.000080 Bright Copper per Mil-C-14550 (2) (over)
.000050 Nickel Strike per QQ-N-290, Class 2 (2)

K. .0003 thick maximum Molybdenum Disulfide in an Alkyd-Epoxy Resin (Drilube Product NO. 90 or equivalent).

NOTES:

(1) Bright Gold Plate on all connector center contacts/pins, male and female, shall be .00005, Class 1.
(2) Thickness is in accordance with Mil-G-45204B, Para 6.3 "Strikes and Underplating".
(3) On aluminum only.
(4) On C'res steel only.

ADAPTERS

Coax, Concentric Twinax, Triax, Quadrax

INTRODUCTION

Pages 42, 43 and 44 contain various adapter tables and a table of adapter circuits. In the tables on pages 42 and 43 an X in any column-row intersection indicates that an adapter is available using the connectors listed in the respective row or column. Any adapter represented by an X requires an appropriate circuit designation from the table on page 44. If a number is present in any row-column intersection the adapter can be ordered by the model number, shown after the table. These adapters do not require a circuit designation since the circuit is fixed, i.e. pin to pin and shield to shield.

Adapters not having either an X or a number in the row-column intersection may be available on special order.

ORDERING INFORMATION

Select a connector from the left hand column and one from the top row. If an X appears in the intersection the part number will be constructed as shown in the following example. If a number appears in the intersection, order by model number shown after the table.

AD-BJ26-K2-BJ50

Adapter
Connector from column (lowest alpha/numeric)

AIRBORNE DIGITAL DATA BUS – MIL-STD-1553B

Application Notes and New Product Release

NEW

• REQUIREMENT

MIL-STD-1553B governs a computerized and multiplexed data distribution system designed for the many functions of command, control, communications and intelligence (C^3I) in military aircraft. By using a single transmission cable instead of the complicated, heavy and dedicated cabling now used, great advantages of additional information, automation and weight saving, necessary for the complex demands of aircraft operations, can be realized. Twinax cable (78 ohm) was selected to provide the transmitted digital information with the needed protection from magnetic and electro static interference including nuclear electro-magnetic pulse (NEMP). Complete shielding of the pair must be maintained along the transmission path including the electrical contacts within multi pin connectors. How TWINAX accomplishes the noise reduction is described in the disertation starting on page 2. For these same reasons, MIL-STD-1553B techniques are also being considered for use in ships, battle tanks, helicopters, missiles and space vehicles in U.S. and other NATO forces as well as the many ground applications such as data networks and perimeter security for airports, armories and other government installations.

TROMPETER ELECTRONICS has been supplying matching components of twinax cable and connectors for 20 years with the intent of improving the transmission capabilities and interference rejection of data transmission systems. New and currently available TWINAX CABLE, CONNECTORS, PATCHING and SWITCHING items, compatible with MIL-STD-1553B requirements for both airborne and ground checkout applications, are listed as follows:

• NEW TWINAX CABLE

A new airborne 200°C, 78 ohm, twinax cable (MIL-C-17/176) has been developed for use with our connectors and contacts. This cable has TFE primary dielectric and PFA outer jacket, 90% minimum shielding coverage and approximately 10 twists per foot of AWG #24 silver plated high strength copper alloy conductors. Also, it has an O.D. of approximately 0.135 inches (3.429 mm) and weighs less than 20 pounds/1000 feet. Attenuation is 1.4 dB/100 feet @ 1 Mhz, less than 4.5 dB/100 feet @ 10 Mhz. and is useable to 30 Mhz. TFE rod fillers are used to lessen the ground shunt capacitive losses, facilitate connector installation and physically round out the cable for more positive environmental sealing. The individual wire dielectrics are color coded blue and white for MIL-STD-1553B or other electrical polarization identification. Standard military and commercial practice utilizes the blue wire for data bus "positive" (HI) polarity connected to the center contact of the concentric twinax connector and the white conductor for "negative" (LO) polarity connected to the intermediate contact. This cable is available as Part #TWAC-78-1F1. It's construction is similar to our TWC-78-1 standard 85°C twinax cable. Specifications for these and other Twinax cable are shown on page 32. Cable samples are available upon request.

• TEI's TWINAX INTERCONNECT SYSTEMS

Catalog listings of TEI's available TWINAX matching connectors, ground cables and related patching/switching equipment are:

1) **Sub-miniature** concentric connectors in the TRS 3 & 4 lug bayonet series and the TTM threaded series, page 36. (½ BNC size). These families of subminiature stand alone connectors **were specifically developed for MIL-STD-1553B requirements** to provide polarized primary and redundant bus needs. They are supplied in both tool crimp and solder/wrench crimp versions to terminate our new airborne 78 ohm twinax cable described above. It should be noted that these families of sub-miniature stand alone connectors are the present mode of bus installation in the A10 aircraft.
2) **Miniature** concentric in the TRB 3 & 4 lug bayonet series and the TRT threaded series, page 34. (BNC size)
3) **Miniature** polarized 2 pin TWBNC 2 lug bayonet series, page 35. (BNC size)
4) **Standard** concentric in the TRC 2 lug bayonet series, page 35. (C size)
5) Sub-miniature concentric **patching,** page 37.
6) Standard concentric **patching,** page 33.
7) Twinax cable and connector cross reference lists, pages 38 & 39.
8) TEI ground installations (PVC) twinax cable specifications, page 32.
9) Twinax accessories, pages 40 & 43.

Contact factory for the latest TWINAX connector and cable developments which are designed as demand warrants.

SWITCHING

A-B Data Switch

INTRODUCTION

Trompeter Electronics has developed modular low-frequency manual switches for coax and twinax digital communication and data applications. Available in both A-B and 1 x 4 configurations, these non-constant impedance switches are designed for use at frequencies up to 15 Mhz, depending upon the application. Each circuit is electrically isolated above ground with the shield and center conductors switched (except as noted). All unused ports are terminated in a resistive load. Switch action is "break before make" with a neutral position provided in the 1 x 4 configuration. Panels are available, as illustrated, for standard 19 inch rack mounting.

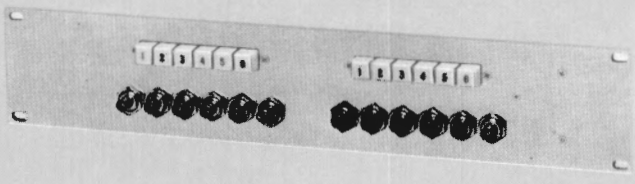
Cross Connect Panel

INTRODUCTION

The DSX-3 panel fills the requirement in signal telephone distribution systems for visually indicating, through lighted pushbutton switches, those circuits that have been interconnected. A total of 12 circuits are incorporated in a standard 3½" x 19" rack panel as shown. That number can be increased to 18 circuits if required.

The tracer circuit is carried through the outer most conductor of the triax interconnect cable to panel ground through the illuminated push button switch.

Voltage limiting is provided to accomodate installation in positive ground systems of either 24 or 48 VDC.



CROSS CONNECT PANEL
DSX-3

CUSTOM PANELS

INTRODUCTION

Trompeter Electronics for years has been unique in the field of custom panel manufacturing. Panels can be configured to meet customer specifications including wiring. Panels may be painted any Fed-Std-595 color and can be either engraved or silk screened. Examples of custom panels are shown below.
